Iodine and iodine compounds are widely applied in medicaments, dyes, energy materials, food additives etc. The development and utilization of iodine resources have attracted much attention. A large amount of iodide is contained in salt lakes of Qaidam Basin and it is of great importance to extract or remove iodide from the salt lakes. Adsorption is a useful and efficient approach to remove or extract iodide from aqueous solution at low concentration.

In this work, a new, stable and effective adsorbent of silver nanoparticles (Ag NPs) loaded on 3-aminopropyltriethoxysilane (APTES) modified glass slides for iodide from aqueous solution was prepared. The influences of initial iodide concentration and co-existing chloride and bromide were investigated. The scanning electron microscopic imaging (SEM) images indicated that the Ag NPs films on the glasses are uniform (Fig. 1). Adsorption results showed that the adsorption amount increased with the initial iodide concentration and the equilibrium was reached in 200 hours (Fig. 2). The energy dispersive spectroscopy (EDS) spectra showed that only iodide was existed on this adsorbing material after adsorption in both iodide solution and iodide, chloride and bromide solution, indicating that the co-existing chloride and bromide were not adsorbed by the adsorbent (Fig. 3).

**Keywords:** iodide, adsorption, silver nanoparticles.
