The Zedang mafic-ultramafic body crops out in the eastern Yarlung-Zangbo suture zone of Tibet. This massif consists of mantle peridotite, gabbro, diabase and volcanic rocks. The mantle peridotites are mostly harzburgite, lherzolite and a few harzburgites with chromitite. Dike-like bodies of dunite are also present. Mineral structures show that the peridotites experienced plastic deformation following partial melting. The Fo values of olivine range from 89.62~91.84 Fo. The orthopyroxenes are from 87.82

to 90.32 En. Clinopyroxenes are mainly endiopside and diopside and the En values of clinopyroxene range from 44.12~50.02. The spinels have Cr# values from 17.00 to 93.59. The aluminum-rich spinels are hosted by harzburgite and lherzolite and the chromium-rich spinels are hosted by dunite. The mineralogy and geochemistry of the Zedang peridotites suggest that they formed originally at a mid-ocean ridge (MOR) and were later modified by suprasubduction zone (SSZ) melts.
